## The under blenge life cycle.

The under blenge actually emerges out of a plant as a little blob.

As the blob starts to no longer become a blob it evolves to a blob with little stumpy legs,

Then the blob is no longer a blob it grows huge long legs and massive legs.

Then the under blenge goes and hides in a rat egg sack and that's where he gets his colour from.

Once the creature has got its colour it hides under a bridge then jumps on lorry roofs and then goes and finds a bee hive to live in.

It steals the honey and then it becomes larger and eats all the bees but the bees stingers stay in its belly he runs away and becomes a baby again.
